COMPLETE SPECIFICATION

Process for Preparing Catalysts and the Catalysts so Prepared

We, NAAMLOOZE VENNOOTSCHAP DE BATAAF-  
SCHE PETROLEUM MAATSCHAPPIJ, of 80 Carel  
van Bylandtlaan, The Hague, The Nether-  
lands, a Company organised under the laws  
of The Netherlands, do hereby declare the  
invention, for which we pray that a patent  
may be granted to us, and the method by  
which it is to be performed, to be particu-  
larly described in and by the following  
statement:—

The invention relates to a process for pre-  
paring catalysts by impregnating a carrier  
material with two metal salts in solution and  
subsequently decomposing these salts.

In some cases a process of this type has  
the drawback that the two metal salts re-  
ferred to above react in the solution with  
each other and form an insoluble compound.  
This not only involves the loss of valuable  
catalytic material but, apart from the possi-  
bility that the catalyst obtained may be less  
active, it also renders effective impregnation  
of the carrier difficult or impossible. Al-  
though it is possible to obviate the losses by  
carrying out the impregnation by using the  
various metal salt solutions one after the  
other, the impregnation itself will only be  
partially improved thereby.

From Fiat Final Report No. 968 it is  
known to prepare zinc-tungsten-silica gel  
impregnation catalysts with methylamine as  
a solubilising agent.

When studying the influence of methyl-  
amine it was found that the precipitate  
which is formed when a 10% aqueous zinc  
nitrate solution is added to a 4% aqueous  
ammonium tungstate solution, does not  
occur when methylamine is added to the  
tungstate solution. A further examination  
revealed that with other salt solutions, such  
as cobalt or nickel nitrate, the use of methyl-  
amine cannot avoid the formation of a pre-  
cipitate.

It has been found that these difficulties  
can be overcome in preparing certain cata-  
lysts from ammonium tungstate or molyb-  
date by using an alkanolamine as a solubili-  
sing agent to prevent the undesirable forma-  
tion of an insoluble compound.

Thus, according to the present invention, 50  
a process for preparing catalysts by impreg-  
nating a carrier material with an aqueous  
solution containing a salt from each of two  
distinct groups, namely a first group consist-  
ing of ammonium tungstate and ammonium 55  
molybdate and a second group consisting of  
cobalt and nickel salts is characterised by  
forming the impregnating solution by mixing  
or contacting a salt of the first group with a  
salt of the second group in the presence of 60  
water and an alkanolamine.

Particularly suitable alkanolamines for the  
purposes of the present invention are mono-  
ethanolamine, di-ethanolamine and tri-  
ethanolamine. 65

In carrying into effect the process of the  
present invention it is preferred to prepare  
first an aqueous solution of ammonium  
tungstate or ammonium molybdate in the  
presence of the alkanolamine and then to 70  
add the cobalt or nickel salt to this aqueous  
solution in order to mix or contact the salts  
with one another. This preference is based  
upon the observation that the alkanolamine  
increases the solubility of ammonium tung- 75  
state and ammonium molybdate in aqueous  
media. Thus it is possible to dissolve in a  
50% aqueous alkanolamine solution at room  
temperature, for example 15% ammonium  
tungstate, whereas in water only a solution 80  
of approximately 4% concentration can be  
obtained at the same temperature. Hence,  
by operating in the preferred manner it is  
possible to obtain a higher concentration of  
catalyst on the carrier material. 85

An alternative way of carrying into effect  
the process of the present invention is to  
mix the appropriate salts with each other in  
the presence of an aqueous alkanolamine  
solution. 90

Suitable carrier materials for the catalyst  
are: silica gel, the German bleaching earth  
known as terrana, kaolin, magnesium sili-  
cate, magnesium carbonate, magnesium  
oxide, aluminium oxide prepared by precipi- 95  
tation and particularly so-called activated  
alumina, as well as other active aluminium  
oxides, such as those prepared by activating

bauxite (for example that known under the Trade Mark Porocel).

After the carrier has been impregnated with the salt solution it is freed from solvent (alkanolamine plus water) by heating, either in vacuo or not, and compressed into pieces, such as pills, tablets or strands of the desired hardness, whereupon the impregnated metal salts are decomposed. The catalyst can subsequently be reduced with gas, particularly hydrogen, at elevated temperature or be subjected to a sulphidising treatment, for example, with hydrogen sulphide.

The catalyst obtained can be used in various reactions such as hydrogenation, dehydrogenation, desulphurisation, hydroforming and reforming.

The following Example will further illustrate how the invention may be carried out in practice, but the invention is not restricted to this Example. The percentages are by weight.

*Example*

A 10% aqueous solution of nickel nitrate was added to a 15% solution of ammonium tungstate in a 50% aqueous monoethanolamine solution. No precipitate was formed, so that the solution could be used for impregnating an aluminium oxide carrier to prepare a catalyst.

Corresponding results were obtained by using cobalt nitrate instead of nickel nitrate, as well as when the tungstate solution was

replaced by an ammonium molybdate solution.

What we claim is:—

1. A process for preparing catalysts by impregnating a carrier material with an aqueous solution containing a salt from each of two distinct groups, namely a first group consisting of ammonium tungstate and ammonium molybdate and a second group consisting of cobalt and nickel salts, characterised by forming the impregnating solution by mixing or contacting a salt of the first group with a salt of the second group in the presence of water and an alkanolamine.

2. A process as claimed in claim 1 in which a solution of a salt of the first group and an alkanolamine is first prepared and a salt of the second group is subsequently added either alone or in solution.

3. A process according to claim 1 or 2, in which mono-, di- or tri-ethanolamine is used as the alkanolamine.

4. A process for preparing catalysts substantially as described with reference to the foregoing Example.

5. Catalysts whenever prepared by the process claimed in any one of the preceding claims.
